I. INTRODUCTION

BY GRAHAM LUSK

Very early in his scientific career, in the year 1877, Atwater turned his attention to the question of the nutrition of the people. The many valuable bulletins published by the United States Department of Agriculture testify to much splendid study into the problems of food for the multitude. And yet little practical use has come of it all. Why then talk about nutrition? A critic writes, "We need food, but do we need books to remind us of our need? And as an unanswerable challenge another critic cries, "Does Professor X eat his own diet?" It is truly stated that normal nutrition is associated with appetite, and it is therefore argued that the appetite is not to be controlled by knowledge. One has only to recall the appetite for drink to realize the utter fallacy of this argument. A glass of beer or a glass of wine taken at the end of a wearisome day is not of demonstrable evil and may be of benefit to the digestion. Yet to follow the appetite when it leads to drink in excess is of injury to the body, the mind and the economic

welfare of the individual and therefore inimical to the welfare of the state.

But why repeat such self-evident truths? Has not enough been said? Are not words wasted in repetition of the obvious? In defense one may recall a scene at the New York Academy of Medicine in which Sir William Osler maintained that the essence of successful teaching consisted in "Reiteration, reiteration, reiteration." One of the audience present qualified this definition by adding the words, "without irritation." If successful teaching be accepted as "reiteration without irritation," let the following presentation be an attempt in that direction.

Food has been defined as a well-tasting mixture of foodstuffs of such a composition that the body is not injured by its use, and of sufficient quantity to maintain the body in good condition.

One may consider this definition under three headings.

1. Value of flavor.
2. Importance of composition.
3. Importance of quantity.

VALUE OF FLAVOR

It is known to all that the sight of appetizing food "makes the mouth water." It is known, however, to comparatively few that the sight of such food "makes the stomach water" in the same sense. That is to say, a flow of gastric juice is set up in the stomach. This flow is accelerated by the actual taste of the food, so that a large amount of valuable digestive fluid is set to flowing merely through the psychic appreciation of flavor. When food is taken without appetite, this important preliminary flow of gastric juice does not take place and proper digestion is rendered more difficult. Not only this, but the glands lying deeper down in the intestines yield their digestive juices in larger measure, the greater the quantity of gastric

juice which passes from the stomach into the intestine. The appetite is like a magic wand influencing the whole of the digestive process. Fear and anger lead to a parched throat, and in an entirely similar manner to a parched stomach, so that food cannot be well digested under these circumstances. It is familiar to all that the sight, smell or sound of anything repellant will cause loss of appetite. The writer has seen an artist faint when an operation of Dr. Carrel became the subject of a dinner conversation where men and women were present. The appetite is favored by the extraneous refinements of civilized life, such as a spotless table cloth. It would also be affected by the cleanliness of the preparation of the food could one always look behind the scenes. It is affected by the atmosphere of cheer at the table. Neither scolding parents nor snarling children facilitate the digestion of the Christmas dinner.

The question of flavor in all its ramifications is therefore a very important one. It is one of the pitfalls of the prescribing physician, because he is very likely to believe that what he likes is excellent and what he detests is bad. The great multitude of people like pickles, but some do not; the latter class must not argue that pickles are therefore injurious. The common foods of life, such as potatoes, tomatoes, and bananas, all have their personal enemies based on dietetic prejudices which are largely imaginary, although as a psychosis the manifestations of repulsion are very real.

IMPORTANCE OF COMPOSITION

A celebrated school mistress once asked that a book be written which would tell her what apple sauce was without introducing the terms protein, carbohydrate and fat. Alas, that is impossible. It would be like teaching architecture without mentioning brick, granite and marble!

But the knowledge is not recondite. Protein is the characteristic solid constituent of muscle. The protein framework is essential for the manifestation of those properties whose aggregate is called life. And besides this, water and salts enter into the organization of the living particles. These salts are as varied as are those of the sea water and they are essential to living things. In vertebrates, salts are further used to build the larger framework of the bones. When various molecules of protein are united in a certain definite order with water and salts, life is possible. If the definite order is disturbed, death results. Life depends on the arrangement of the particles. One recalls the story of the Yankee who, during the winter months, sold a "sure cure for potato bugs" with the caution "not to be opened till wanted for use" and with the promise of instructions for use inside the package. In the summer time, on opening the package the farmer found two small cubes with the directions "place the potato bug on one cube and press firmly with the other." Death not only takes place through such disarrangement of the particles, but also it may follow on the influence of a poison which prevents the proper functioning of the living thing.

A peculiarity of living tissue is that a part of its protein is constantly being broken down and replaced by repairing material. It is as if structural units were constantly being dissolved out of a building and automatically replaced by new ones. In the human body about two and one-half parts out of a thousand of its protein are thus daily renewed. It is as if one structural unit out of every four hundred in a building were replaced with a new one every day. For this reason one must eat protein. This is repair protein to replace that lost in the wear and tear on the machinery of the cells.

Protein is the essential constituent of all meats, fish and eggs; it is a large constituent of milk, and

mixed with fat is the essential constituent of cheese. Protein is not a simple chemical substance, but it may be broken into seventeen different fragments. This is what happens when protein is digested in the stomach and intestines. These fragments are absorbed by the circulating blood and when they are carried to the different tissues the fragments are put together in a manner which is characteristic for each tissue. Suppose each structural unit in a building were made up of seventeen parts, all of them different, such as gold, silver, iron, lead, tin and so on, and when one of these larger structural units went into the scrap heap suppose there were always present a supply of all the several varieties of new parts necessary to build another like it; then one has an analogy of what happens. One might imagine that these seventeen different units might be arranged in different ways, depending on the use to which the particular structural unit was put. In like manner, it comes to pass that the protein of milk is split into fragments in the baby's stomach and these various fragments are absorbed by the blood and are carried by this medium to the different organs of the baby's body, there to build up the structure of each particular organ after its own particular way. The seventeen different chemical units known to occur in protein may be joined together in different ways so that 350 million times a million different combinations are possible even though only a single representative of each unit is used (Abderhalden). In this they resemble the multiplicity of combinations possible with the letters of the alphabet. On account of this it is possible to build liver protein or muscle protein out of milk protein. In the muscles of fish and in the white of egg there are again other variations in the order of those letters of the protein alphabet, and therefore, these proteins are distinctive. These proteins contain all the seventeen units and are therefore capable of repairing any tissue. It has been

suggested that such proteins be called proteins of Grade A.

Proteins are also found in all vegetable foods. The vegetables contain some complete proteins, that is, those which have the full array of seventeen individual units, but they also contain some incomplete proteins, that is, those which are deficient in one or more of the characteristic units which are necessary to build up animal protein. These incomplete proteins have little or no value in nutrition. Thus it comes about that it requires a much larger quantity of vegetable proteins (which include complete and deficient proteins) to maintain the machinery of the body in repair, than when animal protein is given in the form of meat, eggs, fish, milk or cheese.

It must be remembered, however, that when a person is engaged in active labor or excessive exercise he may be able to obtain a very liberal supply of proteins of the higher grade in the large quantity of vegetable foods of which he partakes. This gives a scientific explanation to the saying which has become proverbial, "the railways of the country have been built on beans."

Attention is called to the generally overlooked value of milk protein.

There is no danger of protein undernutrition in this country. The general trend is toward protein extravagance, that is, its ingestion and destruction in excess of the needs of repairing the tissues. This is due to the fact that to most normal men a beefsteak represents the choicest of good things. Here appetite triumphs over reason and economy. If one listens attentively one hears again a rumbling note, "Would Professor X eat his own diet?"

Yet the matter of enormous meat consumption is one of serious economic importance which is not to be lightly tossed aside. The following table prepared by Rubner indicates the quantity of meat consumed

per head of population (adults and children) in the various nations of Europe and also the increase in the consumption of meat in Germany during the last hundred years.

TABLE 1.—RUBNER'S TABLE OF MEAT CONSUMPTION IN EUROPE

	Present Consumption of Meat Per Capita Per Year, Pounds	Consumption of Meat in Germany in Different Years	
		Date	Pounds
Germany.....	115	1912	115
England.....	105	1900	102
France.....	74		
Belgium and Holland.....	75	1892	72
Austria-Hungary.....	64	1873	65
Russia.....	59	1840	48
Italy.....	23	1816	30

There is little doubt that excessive consumption of meat constitutes a grave and unnecessary economic waste. The increased cost of food falls most heavily on this item of indulgence and its ever-increasing price follows as much the law of supply and demand as does the price of champagne, and, for the same reason, the price of flavor for those who have the price. It is part of the spirit that demands the motor car, the luxuries of life as well as its necessities.

As regards the utility of carbohydrate and fat in the food, one may especially attribute to them a value as fuel. They are oxidized in the body and keep the body warm and when work is accomplished they furnish the energy with which to perform it.

The carbohydrates consist in sugars and starches. The latter are convertible into sugars in intestinal digestion. One can speak of cornstarch as equivalent to the sugar into which it is convertible. Cane sugar has essentially the same value in nutrition as starch. The two belong to the same group and yet are not identical, and so the layman must learn the cumbersome term carbohydrate as the common name for the physiologically identical sugars and starches.

The great staple starchy foods include rice, potatoes, bread, beans, macaroni and corn. These are the cheapest food fuels. They all contain protein but their principal constituent is starch, which when converted into sugar is as much a fuel for the body as gasoline is for the automobile.

Fat is taken in the food with most meats. It is largely consumed as lard and also as butter. Nuts contain 50 per cent. of their weight as fat. The fats are a far more costly fuel than the carbohydrates, although they serve a similar purpose in nutrition. The advantage of taking a diet which includes a mixture of carbohydrates and fats lies in the fact that the intestine is not called to excessive effort in caring for the digestion and absorption of a large quantity of a single food material, and that equivalent amounts of fat are less bulky than carbohydrates. The disadvantages of a large use of fat are, first, its original cost, and, second, the fact that its ingestion diminishes the intake of vegetables and hence the amount of cheap vegetable proteins, thereby making fat indirectly a still more expensive food.

There are important accessory factors to be discussed concerning food. These are the fibrous roughage of cellulose, the salts of the diet and the so-called vitamins.

Sylvester Graham used unbolted wheat flour with which to make Graham bread. The cellulose here produces a freer movement of the bowels. Of similar import is the use of spinach, cauliflower, lettuce, cabbage, asparagus and tomatoes. These substances have almost no fuel value, but they can be prepared to serve with large quantities of fats or oils, and they furthermore give flavor and variety to the fare of the table.

The salts of the food are extremely important. Thus, if calcium be withheld from the diet of experimental animals the bones become porous and finally

break. Such conditions are not found in human life, for the foods ingested always contain sufficient salts to replace those lost from the body. It has been found that when meats are oxidized they yield an acid ash, whereas vegetables usually yield an alkaline ash. It has been recently shown by Blatherwick that of all vegetables potatoes yield the greatest amount of alkaline ash for the use of the body, and that this alkali is most effective in dissolving and eliminating uric acid from the system. In the light of this, potatoes are highly desirable, not only in health, but also in the gouty condition. Yet one of the dietetic fads of the day is to eliminate potatoes from the bill of fare, a really absurd practice, always excepting the cases of those individuals who manifest personal repugnance to potatoes.

Finally, there is a class of substances which exists in minute quantities in some foods and little or none in others. This class is called that of the vitamins. Thus, individuals who live almost exclusively on polished rice acquire the disease of beriberi, and a similar monotonous diet of bread develops scurvy. A diet of bread and water does not maintain the strength of the organism and has been used as a disciplinary method. Minute quantities of vitamins are found, for example, in meat, in butter and in unpolished rice, but they are absent or deficient in polished rice, bread and lard. The vitamins are absolutely necessary for the proper harmonious maintenance and growth of the body. This statement should cause no alarm. There is no beriberi in the United States, for here rice does not ever form the dietary mainstay of the individual. There is practically no scurvy, although it has been known to occur in almshouses, where motives either of economy or graft have deprived the inmates of suitable food.

Summarizing, one can state that in the United States there is no protein, or salt or vitamin deficiency in the

habitual diet, and there is plenty of roughage in the form of cabbage, sauerkraut or other vegetable foods available to him that desires it.

THE QUANTITY OF FOOD

Generally speaking, the mass of food ingested serves two functions, the protein is of use in the maintenance and repair of the cell machinery, and the carbohydrate and fat furnish fuel to this machinery that the motions of life may continue. Protein given in excess also serves the purpose of fuel, as do carbohydrates and fat. In the oxidative destruction of these materials in the body heat is liberated. When 1 gram of fat is burned sufficient heat is produced to raise the temperature of 1 liter of water 9.3° C. ($= 16.5^{\circ}$ F.). Since the unit of heat measurement or the *calorie* is that quantity of heat required to raise 1 liter of water 1° C., it follows that 9.3 calories of heat are set free whenever 1 gram of fat is oxidized. The heat liberated in the body when 1 gram of fat is oxidized is exactly the same as when it burns outside the body. The similar value for starch is 4.1 calories per gram. In the case of protein, 4.1 calories are liberated whenever a gram of this material is oxidized within the organism. When, therefore, protein is consumed in excess, the excess has no greater fuel value than an equal weight of starch. Here then are the fuel resources which keep the body warm, maintain the heart and respiration, and the activity of the other organs, and enable the muscles to perform work. Since every machine requires more fuel when it is active than when it is at rest, it follows that the greater the activity of the body the greater will be the requirement for fuel.

The figures in Table 2 may be accepted as estimates of the fuel requirement of a man weighing 156 pounds (70 kilograms) during a twenty-four-hour period:¹

1. Lusk: The Fundamental Basis of Nutrition, Yale University Press, 1914.

It appears from this that that great class of human beings whose business it is to sit at their desks or to watch machinery, and who may walk to and from their work, require 2,500 calories. In their class are included writers, draughtsmen, tailors, physicians and other professional men, clerks, accountants, etc. Mental effort is accomplished without any increase in the quantity of energy required.

Individuals who stand at their work, such as bakers, dentists, car conductors, decorators and glass workers, require about 3,000 calories. If muscular labor be constant, more is required. Thus carpenters making tables and painters painting furniture require 3,300 calories. Farmers require 3,500 calories, stone masons 4,500, lumbermen 5,000 and over, and a man riding in a bicycle race during twenty-three hours requires 10,000 calories a day.

TABLE 2.—DAILY CALORIC REQUIREMENTS OF 156 POUND
(70 K.) MAN

	Calories
Absolute rest in bed without food	1,680
Absolute rest in bed with food	1,840
Rest in bed 8 hours, sitting in a chair 16 hours, with food.....	2,168
Rest in bed 8 hours, sitting in a chair 14 hours, walking two hours, with food	2,488
Rest in bed 8 hours, sitting in a chair 14 hours, vigorous exercise 2 hours, with food	2,982

These are facts which at the present time are scarcely open to dispute. The sorrowful part of it is that outside a narrow circle they are practically unknown. Physicians sometimes starve their patients and the babies entrusted to their care, in blissful and childlike ignorance of what they are doing. The poor, 50 to 60 per cent. of whose income is spent for food, waste their money in the purchase of beautiful labels or relatively expensive and unnutritious foods. A publisher employing several thousand individuals says that his employees buy from choice the products advertised in his magazines. Children of the poor are sent to buy food for the family and the whole expenditure of half the

family's income is effected in an atmosphere of unfathomable ignorance. Yet if one seeks to help, one is informed that one must not meddle with the appetites, and the funny man of the newspaper makes a witticism on the subject of "highbrow" information.

In spite of the inevitable attitude of the humorous editor, it is well to remember the severity of the winter's cold, the lack of employment, the suffering of the poor, which create a situation very far from humorous.

How can relief be given? One suggestion is to sell 1,000 calories of food in a well-balanced ration as cheaply as possible. Beans are cheap. But you don't like beans. Does Professor X eat his own diet? If beans are not acceptable, then how about macaroni and spaghetti? The meal shown in Table 3 is made

TABLE 3.—COMPOSITION OF A RATION CONTAINING 1,000 CALORIES

	Ounces	Calories
Cooked beans.....	7 $\frac{3}{8}$	400
Pork.....	1	234
Bread.....	2 $\frac{1}{2}$	180
Butter.....	$\frac{1}{2}$	103
Milk.....	5	100
Coffee.....	5	...
Total.....		1,017

up of 1,000 calories and contains 16 per cent. of those calories in protein, one-sixth of the protein being in the form of animal proteins of Grade A, and the rest being in vegetable proteins. The remaining 84 per cent. of the calories are nearly equally divided between carbohydrate and fat.

The actual cost price of this meal of hot pork and beans, bread and butter and a cup of hot coffee and milk is 4 $\frac{1}{4}$ cents, excluding labor and rent, but including the coal used. The 2,500 calories required to maintain a man out of work on this diet would cost 10.6 cents a day, or \$38.70 a year. If such a thing as a "submerged tenth" really exists in this country it

would cost \$387,000,000 to feed 10,000,000 men for one year on this diet. The taxation in the United States, city, state and national, is said to be \$4,000,000,000 annually. Ten per cent. of this sum would feed with pork and beans, bread and butter, coffee and milk, 10,000,000 men who are out of work. A similar menu just as cheap can be based on spaghetti flavored with tomato or cheese. It is not argued that a diet based on the cheaper foods is a panacea for all the woes of the world. It is not argued that such diets are the equivalent of caviar, champagne and canvas back ducks, but it is argued that good wholesome simple food should be more available for mankind at a moderate price in hours of adversity and distress than is the case to-day. People should know how they can conserve their resources without detriment to their bodily welfare.

Passing to the consideration of the nutrition of the great mass of the people it seems probable that at the present time no more valuable data can be obtained than those which may be derived from a study of the various food portions sold by the Childs restaurant establishments which are situated in many cities throughout the country. The portions served are standardized, i. e., planned to be uniform in quantity and quality and the prices are the same in all the restaurants. Mr. F. C. Gephart has completed a notable analysis of 350 different portions as they are sold to guests at these establishments. The results of these analyses have been tabulated. Table 4 gives the cost of each food if that particular variety were alone made to furnish the 2,500 calories necessary for a man leading a sedentary life, to which is added the restaurant price of these 2,500 calories and the number of portions necessary to furnish them. Portions which contain 15 per cent. of protein calories or more have received a star. Portions which contain meat, fish, egg or milk proteins are preceded with the letter A,

indicating the presence of animal proteins. The material in this table is arranged in the order of the increasing price of the food. In Table 9 the name material is arranged in alphabetic order.

TABLE 4.—THE COST OF 2,500 CALORIES IN FOODS
ARRANGED IN ORDER OF THEIR INCREASING PRICE

Note that when three portions furnish 2,500 calories, one portion affords a good meal. When nine portions furnish 2,500 calories, then three different portions should form the meal.

Name of Food	Nutritional Calories for Five Cents	Per Cent. in Bread and Butter	Cost of 2,500 Calories	No. of Orders to Make 2,500 Cal.
Napoleon	453.6	\$0.28	6

† Not purchased in the restaurant.

It appears that fourteen different orders yield enough food fuel for one day at a cost of less than 40 cents, or less than \$145 per annum. Of these the roast beef sandwich made as a roll is conspicuous for cheapness.

Thirty-three different portions may yield the total energy requirement of 2,500 calories at a cost of less than 50 cents per day.

Suppose a restaurant be established with these thirty-three varieties only, and the consumer arranged his dietary so that he paid an average price of 40 cents for 2,500 calories, it would cost him \$145 per annum

for his food. If it be a fair division of one's income to expend one-fourth for rent, one-fourth for clothes, one-fourth for food and one-fourth for extras, then a single man may live at a Childs restaurant when his income is \$50 a month, of which he spends \$12.50 for food if he restricts himself to those thirty-three varieties. As a married man he would require \$100 a month to maintain himself and his wife under similar circumstances.

Passing to food of a higher cost, it appears that thirty-two portions yield 2,500 calories at a cost of between 51 and 60 cents and here portions containing meat predominate.

There are forty-two varieties of foods which yield 2,500 calories between 61 and 70 cents and thirty-three which cost between 71 and 80 cents. At this latter level of cost orders for eggs such as fried eggs and creamed eggs on toast begin to appear.

Twenty varieties yield 2,500 calories at a cost of between 81 and 90 cents and twenty-four varieties cost between 91 cents and \$1.00. The sirloin steak appears at the level of 91 cents.

This gives a choice of 184 dishes which yield 2,500 calories at a maximum daily cost of \$1.00.

There are fifty-five varieties of food which cost more than \$1.00 per 2,500 calories. The cost rises rapidly. Seven orders of two boiled eggs (with buttered toast) costing \$1.03 for 2,500 calories stand out in their extravagance, but this is outdone by nine orders of two poached eggs on toast costing \$1.91 for the day's requirement. The portion of spaghetti with cheese is certainly overpriced, and were the service to an Italian clientele would not be so costly.

The greatest wonder appears in the cost of the tomato portions. Tomatoes with lettuce and dressing cost over \$9.00 for 2,500 calories, nearly as much as cantaloupe at \$10.00, while champagne (bought out-

side the restaurant at \$4.00 a quart) costs \$14.00 for 2,500 calories.

The mystery of tomatoes is baffling. A can of tomatoes is little else than flavored water. The popularity of the tomato probably depends on its flavor and its color. A painter wishing to sell a landscape puts a figure with a red cloak in the center. It is an ancient device. In like manner, a restaurant puts a few lettuce leaves on a plate with a red tomato in the middle, covers it with a little dressing and gets a large price. It is the work of an artist for a connoisseur.

To indicate the practical value to which this work may be put, the following selected menus have been arranged. They give the cost and caloric content of inexpensive dishes which may be ordered at the restaurant and which provide for three meals a day during a week for a man of average weight. Only the morning cup of coffee occurs more than once.

Per month.....	16.80	

Individual income appropriate to this expenditure is \$67.20 per month.

At Bellevue Hospital, New York, in 1912, the cost of food from the market, that is, of uncooked food, was 25 cents daily for 3,200 calories for each person in the establishment; at the Muncipal Lodging House during 1911 the cost was 13 cents daily for 2,700 calories per person.

When one considers that Childs restaurant pays for service and for expensive ground floor rental in the busiest parts of New York City, surely food at the cost outlined above is not expensive. But this menu is laboratory made, calculated from the scientific standpoint and from the standpoint of food economics. The restaurant in question could easily give this information on its menu card. It would have immense educational influence were it to do so.

In a few selected portions Mr. Gephart has estimated the retail market value of materials entering into the portions sold and these are revealed in Table 6.

It is evident that the actual cost of these standard portions is about half to one-third their cost in the restaurant. The housewife who knows how to buy the essential ingredients, and especially how to cook them, is an economic factor of prime importance in the home. Of such stuff is the science of food economics.

Mr. Gephart's work is the first extended investigation of its kind. It would be wise if the public could be better informed regarding the caloric value of foods which it purchases. It would be of vast significance if the barrel of flour, the can of lard, the pot of beans or the package of breakfast food could be labeled with the caloric content of the particular unit of sale.

The question would not then be asked, would Professor X eat his own diet? But the individual could then ask himself, am I sufficiently well-to-do to be careless of what I spend for food? And, can I spend less with equal profit and as great satisfaction?

THE COST OF READY-TO-SERVE FOODS IN NEW YORK CITY, BASED ON THEIR ENERGY CONTENT PER UNIT OF PRICE

F. C. GEPHART

Chemist of The Russell Sage Institute of Pathology, in Affiliation with
the Second Medical Division of Bellevue Hospital

II. DESCRIPTION OF METHODS

At the suggestion of Dr. E. F. Du Bois and with the earnest cooperation of Professor Lusk, an investigation of the food value of the different portions or "orders" of food served in the Childs restaurants or stores in New York City was undertaken during the spring and summer of 1913, for the purpose of determining the actual energy value of the different orders, that they might all be reduced to a common unit for comparison of their relative cost from the nutritional standpoint. The above named chain of stores was chosen because it was thought that they were probably the most representative of their kind in the city and because they undoubtedly serve a great mass of people. In this manner it was hoped to obtain valuable data concerning the composition and energy content of the various kinds of food that are actually chosen by the people for consumption.

Especial acknowledgment is due Mr. Rudolph H. Harries, whose painstaking accuracy has been of valuable service in the accomplishment of the work.

Atwater and Bryant afforded the first real stimulus to a clear understanding of the composition and nutritive values of American foods when they compiled the reliable data that had been previously published in

this country, together with data collected by themselves after numerous analyses, and published it entire in the form of a government bulletin entitled "The Chemical Composition of American Food Materials."

Prior to the appearance of this work and the numerous other works incorporated therein, almost all of our information came from abroad, and it is obvious that its application must necessarily have been limited when applied to American materials. The tables of Atwater and Bryant contained almost all the information one could ask regarding the composition of foods purchased on the open market, both cooked and oftentimes uncooked, the percentages of moisture, protein, fat, carbohydrate and ash being included, and, lastly, but of great importance, the calorific values per pound of material.

From a persual of these tables, however, one cannot learn the quantities of the various articles that are ordinarily considered a portion, nor can one learn the cost of the same nor the auxiliaries that are usually served in what would constitute an order. When the composition of a foodstuff is compared before and after cooking quite a few changes may be noted, not only those brought about by the process of cooking, such as the coagulation of protein, the solution of several ingredients in water, either wholly or in part, or the partial loss due to the decomposition of fat, but also the changes in the food value due to the addition of auxiliary materials, such as fat, flour, sugar, etc., to say nothing of salt, pepper, and various spices and flavors, thereby presenting a much different composition when ready for consumption than when purchased or prepared for cooking.

With a hope of determining the actual values for foods prepared for immediate consumption, this investigation was undertaken.

In the City of New York there are forty-six (46) Childs restaurants all dispensing foods prepared at

the commissary department in a systematic way, the only essential divergence being in a few orders that are prepared in the individual restaurants. Bills of fare are not identical in the several restaurants, some present a greater variety than others, but as a whole they may be considered as emanating from one large restaurant. When these points were clearly established, a plan of collecting samples was finally decided upon. It was found that it was possible to secure bills of fare in advance, in some cases many days in advance, so that we were able to compare the articles served at the different places and formulate a list of foods to be secured to complete as far as possible a collection of all orders served. It is a common practice in these restaurants to serve orders to be taken out, the only requisite being that a deposit of five or ten cents be paid on each dish and refunded at the time the dishes are returned to the restaurant. This was the plan followed, and as far as we know, all samples were collected without the knowledge of the management. Every restaurant at that time in the city was visited, at least one order secured, often more than one, and after the whole field had been covered, our efforts were concentrated on those restaurants that we considered the most representative of the company, and in these few places many duplications of the more popular orders were procured. Several orders, usually those which could be most easily transported, were secured from seventeen (17) restaurants outside of the city, but as these samples showed no material differences from those purchased in New York City, it was decided to enter them in one general table.

In all, approximately three hundred and fifty (350) orders were collected and analyzed. These do not represent the entire offering of the restaurants, but practically everything. In quite a few instances we noticed an article that we were unable at a later date

to secure. We were careful not to purchase an article until the season for such was well established, attempting in this way to secure such things at their usual dispensing prices, and not at the price that they command on their first appearance. Unusual courtesies was shown in practically all the restaurants visited, in several instances care was even taken to furnish us with salt and pepper in separate packets.

When the samples were received at the laboratory, serial numbers were assigned, the several ingredients were weighed individually (when possible), the entire order transferred to a glass or porcelain container, dried either in a vacuum desiccator over sulphuric acid, or, in the case of orders containing much water, on the steam bath, allowed to remain in contact with the air for several hours, weighed, passed through a food chopper several times until they were uniform, and when low in fat finally meshed and bottled for analysis. The analysis consisted in the determination of moisture, which was done by weighing two or three grams of the material into a small lead bottle cap, such as is used in the trade for crimping the heads of catsup bottles and the like, placing the cap and contents in a vacuum desiccator over sulphuric acid where, with frequent agitation, it was allowed to remain for two weeks, after which it was removed, reweighed, folded, placed in an extraction cone and extracted with anhydrous ether in a Soxhlet extractor for two days, the ether removed, and the residue weighed as fat in the usual way. The protein was determined by the well-known method of Kjeldahl; the heat combustion in the Riche bomb calorimeter (*Journal American Chemical Society*, xxxv, No. 11, 1913).

Inasmuch as the first practical application of this apparatus was made in this work, and also because the apparatus differs somewhat from all other bomb calorimeters, it does not seem out of place to give

a very brief description of it here. In calorimetric work the amount of heat liberated by a given weight of substance burned in an excess of oxygen, is measured. In this particular type of apparatus this measurement is effected with the aid of a vacuum cup through which there has been found to be no measurable radiation of heat. The weighed sample is placed in the bomb, the bomb charged with oxygen at about thirty atmospheres pressure, immersed in the weighed water and when the temperature of the system has become constant the sample is fired. The ignition is brought about by overloading a four ampere fuse wire by the use of a small platinum wire attached to the supports immediately above the sample within the bomb. Two small linen threads attached to the platinum wire affords contact with the sample and assures its ignition. It is obvious that the use of this method insures constancy in the heat of ignition. The maximum thermometer reading is recorded in about five minutes after ignition. The calculation is indeed simple, the rise in temperature in degrees multiplied by the hydrothermal equivalent of the apparatus, minus the heat of ignition and that liberated by the nitric acid formed during the combustion, gives the calories of heat liberated in the combustion of the sample taken. Four combustions were regularly completed in an hour's time, requiring the services of only one person and necessitating the reading of a single thermometer. This apparatus is extremely accurate.

Carbohydrate was estimated by difference in heat as measured in the bomb and that calculated from the sum of the heat of combustion of the protein and fat as found by analysis, using the factor of Stohman for the calculation of the mean heat of combustion of protein in the bomb as being 5.71 calories per gram and that of fat as 9.3 calories per gram. This means of estimating carbohydrate has never before been employed, as far as we are aware, and we feel that

it is especially valuable in the analysis of materials containing large amounts of fat and protein, both of which must be removed before attempting the determination of starch by the usual methods. This procedure gives total carbohydrates, fiber being included, but in almost all of our samples the amount of fiber was negligible, with the possible exception of fruits and vegetables, which were few in number.

Preservatives and adulterations were tested for in all samples of milk and cream, with negative results.

III. KEY TO TABLE 7

Column 1.—Shows the name of the order or kinds of food which we have classified alphabetically for convenience. (In all cases in which duplications of orders were made, the number of orders from which the mean values were calculated is indicated, as well as the percentage variations of the several ingredients, both above and below the mean, and the percentage variations above and below the mean for the several calculated and determined factors are also shown in the respective columns to which they refer.)

Column 2.—The constituent parts of the order, as far as it was possible to separate them. (Bread was usually spread with butter.)

Column 3.—The weights in grams of the constituents as they were received in the laboratory.

Column 4.—The cost of the order.

Column 5.—The gross heat of combustion of the order in large calories as measured in the bomb.

Column 6.—The heat of combustion in large calories that the protein fraction of the order furnishes in the bomb.

Column 7.—The heat of combustion in large calories that the protein fraction of the order produces in the body, the so-called protein nutritional calories.

Column 8.—The heat of combustion in large calories that the fat fraction of the order furnishes in the bomb as well as that produced in the body.

Column 9.—The heat of combustion in large calories that the carbohydrate fraction of the order furnishes in the bomb as well as that produced in the body, with the possible exceptions previously noted.

Column 10.—The gross heat of combustion of the order in large calories as measured by the bomb for that fractional part of the order purchasable for 5 cents, or $\frac{5}{4} \times .05$.

Column 11.—The total nutritional calories contained in that fractional part of the order purchasable for 5 cents or $\frac{7 + 8 + 9}{4} \times .05$ or $\frac{5 - (6-7)}{4} \times .05$.

Column 12.—The percentage of the total nutritional calories of the order furnished by the so-called protein nutritional calories or $\frac{7}{5 - (6-7)} \times 100$.

Column 13.—The percentage of the total nutritional calories of the order furnished by the fat fraction either in the bomb or body, or $\frac{8}{5 - (6-7)} \times 100$.

Column 14.—The percentage of the total nutritional calories of the order furnished by the carbohydrate fraction either in the bomb or body (except as previously noted), or $\frac{9}{5 - (6-7)} \times 100$.

Column 15.—The percentage of the total nutritional calories of the order furnished by the bread and butter contained therein. This factor is only an approximation, because of the fact that it is based on the assumption that in all orders containing bread and butter, the bread and butter bore the same ratio to each other as was the case in the sample analyzed to establish this factor, which is probably not true in all cases. As previously stated, the bread in nearly every case was spread with butter, the quantity of the latter appearing to be the same throughout.

Column 16.—Classification of the orders.

We have classified these orders into eleven classes in order that we might be able to strike a mean for each class, namely, meats (steaks, chops, ham and eggs, hash, etc.), pastry and dessert, eggs, sandwiches, fruits, soups, dairy dishes, beans, oysters, salads and miscellaneous.

In making this classification we have classed several orders in two different classes, as, corned beef and beans is classed both as meat and beans, etc., because of the fact that the classification is arbitrary and does not signify that the order consisted wholly of meat or beans, but in a few instances this is actually the case.

IV.—TABLE 7.—ANALYSES OF

VI. DISCUSSION OF RESULTS

Of forty-seven (47) orders classed as pastry and dessert there was obtained a mean of 233.0 nutritional calories for 5 cents, the highest of the class being Napoleon with 453.6 calories and the lowest strawberry shortcake with 91.8 calories.

Of twenty-four (24) orders classed as beans there was obtained a mean of 204.5 nutritional calories for 5 cents, the highest of the class being Boston baked beans with 307.6 calories and the lowest Boston beans "on the side" with 133.7 calories.

Of fifty-six (56) orders classed as sandwiches there was obtained a mean of 180.3 nutritional calories for 5 cents, the highest of the class being roast beef sandwich with roll with 357.8 calories and the lowest sliced chicken sandwich with 78.1 calories.

Of twelve (12) orders classed as dairy dishes there was obtained a mean of 174.4 nutritional calories for 5 cents, the highest of the class being milk crackers with 317.1 calories and the lowest cream of wheat with 63.0 calories.

Of eighty-seven (87) orders classed as meats there was obtained a mean of 174.1 nutritional calories for 5 cents, the highest of the class being lamb croquettes and mashed potatoes with 291.4 calories and the lowest deviled crab with 83.0 calories.

Of forty-four (44) orders classed as miscellaneous there was obtained a mean of 164.7 nutritional calories for 5 cents, the highest of the class being corn muffins with 342.2 calories and the lowest tomatoes and lettuce with dressing with 13.5 calories.

Of six (6) orders classed as oysters, there was obtained a mean of 149.4 nutritional calories for 5 cents, the highest of the class being oyster pie with 220.4 calories and the lowest raw oysters with 18.6 calories.

Of thirty-three (33) orders classed as eggs there was obtained a mean of 140.7 nutritional calories for

5 cents, the highest of the class being plain omelet with 231.5 calories and the lowest two poached eggs on toast with 65.6 calories.

Of four (4) orders classed as salads there was obtained a mean of 135.9 nutritional calories for 5 cents, the highest of the class being potato salad with 217.0 calories and the lowest crab meat salad with 99.5 calories.

Of seventeen (17) orders classed as soups there was obtained a mean of 116.0 nutritional calories for 5 cents, the highest of the class being beef stew with 251 calories and the lowest tomato soup with rice with 36.6 calories.

Of fourteen (14) orders classed as fruits there was obtained a mean of 88.8 nutritional calories for 5 cents, the highest of the class being baked apple with cream with 196.0 calories and the lowest cantaloup with 12.1 calories.

The order containing the highest number of nutritional calories for 5 cents was Napoleons, containing 453.6 calories, and the lowest cantaloup with 12.1 calories for 5 cents.

The order containing the highest number of nutritional calories regardless of cost was tenderloin steak with onions with 1,351 calories and costing 60 cents, the lowest sliced pineapple with 35.3 calories and costing 5 cents.

Of the orders containing bread the fractional part of the nutritional energy of the order from this source averages 43.7 per cent. of the total.

An analysis of champagne is included in the list merely for comparison with the low orders of fruits and vegetables. The champagne (a pint of Mumm's extra dry) was purchased at Charles & Company. It has been assumed in the calculation in the analysis of this item that the alcohol content is used quantitatively as energy. The energy content of a cup of coffee was

determined, and attention is called to the fact that the sample contained both cream and sugar. In cases of so-called breakfast foods, the values given herein represent values as purchased in the restaurant, and not those which would have been obtained by purchasing in original packages.

Table 9 shows the cost of 2,500 calories, each order having been calculated to this unit for comparison. This has been done because a man of average weight leading a sedentary life requires 2,500 calories daily to maintain him in health and strength.

The estimated wholesale cost of ingredients per portion was calculated by Miss Laura A. Cauble, special investigator, Bureau of Food Supplies, Association for the Improvement of the Conditions of the Poor. This was done in order that the housewife could realize the actual cost of such orders in case care is exercised in the purchasing of supplies. Wholesale instead of retail prices were used because of the variation of the latter in different localities. The basis of these calculations were obtained from the appended Table 10, showing the wholesale cost of food supplies. In calculating the wholesale cost of ingredients, no allowance has been made for labor, fuel, rent, etc., the cost as shown being the estimated wholesale cost of the raw materials.

A study of Table 9 shows that the majority of the orders are reasonably cheap, for the cost of maintenance, that is, 2,500 calories, by means of the common and popular orders, usually falls between 50 cents and \$1.00. Table 11 shows a summary of the cost table and hardly requires an explanation. It will be seen that each of 34 orders supplies 2,500 calories for 50 cents or less, 18 of the number being classed as pastry and dessert; each of 157 orders supplies 2,500 calories for 50 cents to \$1.00, 60 of which are meat orders; each of 39 orders supplies 2,500 calories for \$1.00 to \$1.50, 10 of which are meat orders.

Thirty-four per cent. of orders costing \$1.00 or less per 2,500 calories were meat orders.

For 50 cents to \$1.00, 2,500 calories were secured in 63 per cent. of all orders.

In view of the fact that 80 per cent. of all the orders purchased by us supplied 2,500 calories for \$1.00 or less, and that 35 per cent. of this number were meat orders, it can hardly be argued that we are in the midst of the "high cost of living."

Attention should not be diverted from the fact that a few orders are extremely high in cost, but these should be especially noted. They are few in number and are the price of flavor.

Table 12 is a classified list of portions arranged in groups according to their caloric value and lends an easy means of dietary regulation. It is possible at a glance to choose a number of articles to total the desired food value of the meal, noting in each instance the individual food value in round numbers of the portion as well as the cost.

A study of the general table will show well balanced rations and a mean of all orders purchased shows that 13.2 per cent. of the total heat is derived from protein, this being an excellent physiologic mean.

TABLE 9.—COST OF 2,500 CALORIES
